

If you increase the number of hidden layers in a Multi Layer Perceptron, the classification error of test data always decreases. True or False?

True

False

This is not always true. Overfitting may cause the error to increase.

Quiz

In a neural network, knowing the weight and bias of each neuron is the most important step. If you can somehow get the correct value of weight and bias for each neuron, you can approximate any function. What would be the best way to approach this?

- 1. Assign random values and pray that they are correct
- 2. Search every possible combination of weights and biases till you get the best value
- 3. Iteratively check that after assigning a value how far you are from the best values, and slightly change the assigned values values to make them better
- 4. None of above

Birkbeck, University of London

4

Which of the following statement is the best description of early stopping (a.k.a stopped learning)?

- A. Train the network until a local minimum in the error function is reached

 B. Simulate the network on a validation dataset after every epoch of training. Stop training when the generalisation error (out of sample error) starts to increase
- C. Add a momentum term to the weight update so that training converges more quickly
- D. A faster version of backpropagation, such as the `Quickprop' algorithm (Newton's method).

Quiz

What are the steps for using a gradient descent algorithm?

- 1. Calculate error between the actual value and the predicted value
- 2. Reiterate until you find the best weights of network
- 3. Pass an input through the network and get values from output layer
- 4. Initialise random weight and bias
- 5. Go to each neurons which contributes to the error and change its respective values to reduce the error
- A. 1, 2, 3, 4, 5
- B. 5, 4, 3, 2, 1
- C 3, 2, 1, 5, 4 D.) 4, 3, 1, 5, 2

In training a neural network, you notice that the loss does not decrease in the few starting epochs.

The reasons for this could be:

- 1. The learning rate is low
- 2. Regularization parameter is high
- 3. Stuck at local minima

What according to you are the probable reasons?

- A. 1 and 2
- B. 2 and 3
- C. 1 and 3
- D. Any of these

Intrusion Detection in 802.11 Networks: Empirical Evaluation of Threats and a Public Dataset

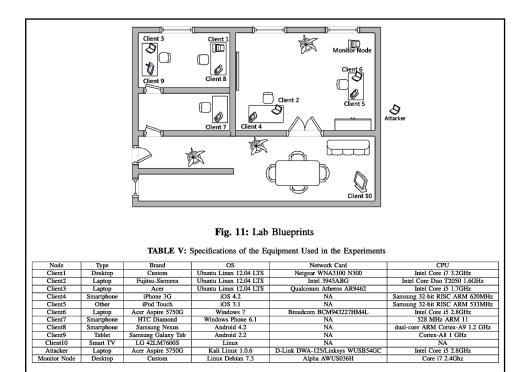

Constantinos Kolias, Georgios Kambourakis, Angelos Stavrou, and Stefanos Gritzalis

Abstract—WiFi has become the de facto wireless technology for achieving short to medium-range device connectivity. While early attempts to secure this technology have been proved inadequate in several respects, the current, more robust, security amendments will inevitably get outperformed in the future too. In any case, several security vulnerabilities have been spotted in virtually any version of the protocol rendering the integration of external protection mechanisms a necessity. In this context, the contribution of this paper is multi-fold. First, it gathers, categorizes, thoroughly evaluates the most popular attacks on 802.11, and analyzes their signatures. Second, it offers a publicly available dataset containing a rich blend of normal and attack traffic against 802.11 networks. A quite extensive first-hand evaluation of this dataset using several machine learning algorithms and data features is also provided. Given that to the best of our knowledge the literature lacks such a rich and well-tailored dataset, it is anticipated that the results of the work at hand will offer a solid basis for intrusion detection in the current as

of availability attacks but more importantly to attacks that threat the secrecy of its key, jeopardising the confidentiality of the entire communication. Posterior efforts such as WiFi Protected Access (WPA) and WPA2 proved to be more robust as far as confidentiality is concerned. However, with the increasing computational power and the instalment of low-cost cluster computing this will be soon inaccurate. Naturally, these mechanisms are anticipated to render themselves vulnerable even to brute force attacks [3]. On the other hand, cloud-based systems like CloudCracker [4] can test 300 million possible WPA passwords in just 20 minutes.

In any case, WPA/WPA2 share almost the same vulnerabil-

In any case, WPA/WPA2 share almost the same vulnerabilities as the early WEP versions as far as availability is concerned. Even the newest amendment, 802.11w [5], which concentrates in patching availability related shortcomings (leading

ABSTRACT

ABSTRACT

Recent studies have proposed that traditional security technology—involving pattern-matching algorithms that check predefined pattern sets of intrusion signatures—should be replaced with sophisticated adaptive approaches that combine machine learning and behavioural analytics. However, machine learning is performance driven, and the high computational cost is incompatible with the limited computing power, memory capacity and energy resources of portable IoT-enabled devices. The convoluted nature of deep-structured machine learning means that such models also lack transparency and interpretability. The knowledge obtained by interpretable learners is critical in security

Abstract—The recent advances in mobile technologies have resulted in Internet of Things (107)-enabled devices becoming more pervasive and integrated into our daily lives. The security challenges that need to be overcome mainly stem from the open nature of a wireless medium, such as a Wi-Fi network. An impersonation attack is an attack in which an adversary is disguised as a legitimate party in a system or communications protocol. The connected devices are pervasive, generating high-dimensional data on a large scale, which complicates simultaneous detections. Feature learning, however, can circumvent the potential problems that could be caused by the large-volume nature of network data. This paper thus proposes a novel deep-feature extraction and selection (D-FES), which combines stacked feature extraction and selection (D-FES), which combines stacked feature extraction and selection (D-FES), which combines stacked feature extraction and selection (D-FES), which combines tracked feature extraction and selection (D-FES), which combines tracked feature selection inspired by an existing shallow-structured machine learner. We finally demonstrate the ability of the condensed set of features to reduce the bias of a machine learner model as well as the computational complexity. Our experimental results on a well-referenced Wi-Fi network benchmark data set, namely, the Aegean Wi-Fi Intrusion data set, prove the usefulness and the utility of the proposed D-FES by achieving a detection accuracy of 99.918% and a false larm rate of 0.012%, which is the most accurate detection of impersonation attacks reported in the literature.

I. INTRODUCTION

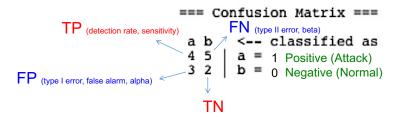

THE rapid growth of the Internet has led to a signifi-cant increase in wireless network traffic in recent years. According to a worldwide telecommunication consortium [1], proliferation of 5G and Wi-Fi networks is expected to occur in the next decades. By 2020¹ wireless network traffic is anticipated to account for two thirds of total Internet traffic — with 66% of IP traffic expected to be generated by Wi-Fi and cellular devices only. Although wireless networks such as IEEE 802.11 have been widely deployed to provide users with mobility and flexibility in the form of high-speed local area connectivity, other issues such as privacy and security have raised. The rapid spread of Internet of Things (IoT)-enabled devices has resulted in wireless networks becoming to both passive and active attacks, the number of which has grown dramatically [2]. Examples of these attacks are impersonation, flooding, and injection attacks.

An Intrusion Detection System (IDS) is one of the most common components of every network security infrastructure [3] including wireless networks [4]. Machine-learning techniques have been well adopted as the main detection algorithm in IDS owing to their model-free properties and learnability [5]. Leveraging the recent development of machine-learning techniques such as deep learning [6] can be expected to bring significant benefits in terms of improving

Detection Rate Vs False Alarm

- Detection Rate is a measure of positive cases that test positive
 - the ratio of TPs to the sum of TPs and FNs == TP/(TP+FN)

```
(1 – Type II Error) // sensitivity = TP rate (# of TPs divided by the total # of positives)
```

- False Positive/Alarm (Type I Error) is a measure of negative cases that test positive
 - the ratio of FPs to the sum of FPs and TNs

```
(1 – Specificity) == FP/(FP+TN)
```

// specificity = TN rate (# of TNs divided by the total # of negatives)

- If a test has a high sensitivity, IDS accurately recognises attack traffics as being attack (TPs).
- If a test has a high specificity, IDS accurately recognises normal traffics as being normal (TNs).
- What if a test has a high Type II Error (FN/(FN+TP))?

Birkbeck, University of London

31

© Copyright 2019

31

Matthews Correlation Coefficient

$$\text{MCC} = \frac{TP \times TN - FP \times FN}{\sqrt{(TP + FP)(TP + FN)(TN + FP)(TN + FN)}}$$

- The MCC is used in ML as a measure of the quality of binary (twoclass) classifications.
- It is generally regarded as a balanced measure which can be used even if the classes are of very different sizes.
- The MCC is in essence a correlation coefficient between the observed and predicted binary classifications;
- It returns a value between -1 and +1.
 - A coefficient of +1 represents a perfect prediction,
 - 0 means no better than random prediction and
 - -1 indicates total disagreement between prediction and observation.

Task to be completed

 Your task is to build a predictive model (i.e. a machine learning classifier) capable of distinguishing between "bad" traffic, called intrusions or attacks, and "good" normal traffic.

Birkbeck, University of London

34

© Copyright 2019

34

Tasks to be completed

This is a group task with individual element, and you will work in a group of 5 students.

- · Team forming
- Planning
- · Searching literature
- · Pre-processing
- Selecting features
- · Exploring and selecting ML algorithms
- · Refining ML algorithms
- · Evaluating model and analysing the results
- · Future work

Birkbeck, University of London

35

Team forming

This is a group task with individual element, and you will work in a group of 5 students.

- Find your partners as soon as possible, and when a group is formed email the module leader (paul@dcs.bbk.ac.uk).
- The module leader will update info on VLE so we know who has partners and who does not.
- Teaching assistants also has support for soliciting partners.
- If you are having trouble finding partners, ask the teaching staff, and we will try to find you a group in a fair way.

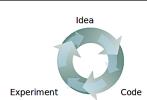

Birkbeck, University of London

36

36

Planning

AML is an iterative process.

• ML projects are highly iterative; as you progress through the ML lifecycle, you'll find yourself iterating on a section until reaching a satisfactory level of performance, then proceeding forward to the next task (which may be circling back to an even earlier step).

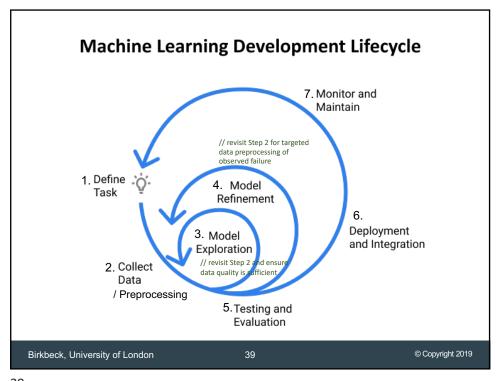

- · You need to plan carefully.
- You need to determine scope, resources, major tasks (and who is responsible for what) and schedule (e.g. Gantt chart).
- You may also need to discuss general model tradeoffs (accuracy vs speed).
- Read "How to plan and execute your ML and DL projects"

URL: https://blog.floydhub.com/structuring-and-planning-your-machine-learning-project/

Birkbeck, University of London

37

© Copyright 2019

Searching Literature

You are suggested to undertake a literature search.

- This is a search designed to identify existing research and information on IDS using AWID dataset.
- Their findings will be very helpful for your task (particularly in feature and algorithm selection tasks).
- There should be no separate literature review section in your report.

Birkbeck, University of London

40

Dataset

- The dataset for this project is available in VLE.
 - Use train imperson without4n7 balanced data.csv for training
 - Use test_imperson_without4n7_balanced_data.csv for testing.
- The first row of each dataset gives variable numbers (this may need to be removed).
- Each dataset has 152 input variables and 1 target variable.
- Please be noted that two features numbered 4 and 7 (*frame.time_epoch* and *frame.time_relative*) have been removed from both datasets as they provide temporal information which may cause unfair prediction.
- The training set has 97,044 observations while testing set has 40,158 observations.

Birkbeck, University of London

41

© Copyright 2019

41

Preprocessing

Use suitable descriptive statistics and visualisation

- · Existing studies focused on algorithms and features only.
- You need to consider various data pre-processing techniques such as data transformation, discretisation, cleaning, normalisation, standardisation, smoothing, feature construction, etc and use them if necessary.

Birkbeck, University of London

42

© Copyright 2019

Selecting features

Go beyond lectures and lab manuals!

- Consider various techniques within each of filter, wrapper and embedded methods.
- Consider some dimensionality techniques linear and non-linear
 - PCA, Factor analysis and LDA
 - MDS, Isomap, LLE, HLLE, Spectral Embedding, t-SNE
 - · Autoencoder, GAN
- Findings from literature review may also be helpful.
- Two features (4. *frame.time_epoch* and 7. *frame.time_relative*) have been removed from the dataset temporal information

43

Exploring and selecting ML algorithms

- · Select candidate algorithms.
- Establish baselines for model performance and start with a simple model using initial data pipeline.
- · Discuss your selection strategies.

Refining algorithms

Finding the best configuration for ML hyperparameters in such a high dimensional space is not a trivial challenge.

- Consider
 - model design components (e.g. # of layers, # of units per layer, loss function, activations, optimisers, dropout layer etc)
 - hyperparameters (e.g. learning rate, dropout rate, batch size etc).
- Perform model-specific optimisations and Iteratively debug model as complexity is added.
- Reproducibility consistency in results
 - ML algorithms are stochastic in nature.
 - Accuracy of 90% today but you may get \pm 1% change in accuracy with the same architecture.

Evaluating model and analysing the results

- · Evaluate the classification performance
 - e.g. accuracy, detection rate, false alarm, type II error, MCC and TBM and TTM – go beyond these measures if necessary
 - · Interpret the results
 - Compare the chosen model's performance with the benchmarks

Future work

This is a place for you to explain where you think the results can lead you.

- What are the strengths and weaknesses of your work?
- · What do you think are the next steps to take?
- · What other questions do your results raise?
- Do you think certain paths seem to be more promising than others?
- This lets people know what you're thinking of doing next and they may ask to collaborate if your future research area crosses over theirs.

Deliverables Required and Submission Information

- A report of 4,000 words (±10%) which includes
 - 2 groups components (i. Planning and ii. Future work) and
 - 5 individual components (i. Pre-processing, ii. Selecting features, iii. Exploring and selecting ML algorithms iv. Refining algorithms and v. Evaluating model and analysing the results).
- A group project you need to work together
 - Each person needs to be responsible for one individual task and drafting the section.
- The cover page show who is responsible for each individual component and wordcount.
- Substantial tables and figures (make a good use of appendix) help to cram all your information into the word count.
- · Arial 10 point or Times New Roman 11 point font
- · 1.5 line spacing.
- A minimum of 2.54 (1 inch) margins
- IEEE referencing must be used, for guidance see: https://ieeeauthorcenter.ieee.org/wp-content/uploads/IEEE-Reference-Guide.pdf
- Your code must also be submitted along the report. It should be either .ipynb or .py.

Estimated Time to Complete

- There will be time that is allocated for working on your group project in Weeks 7 and 8.
- However, it is your responsibility to allocate an appropriate amount of time to this piece of work and to form a group.
